Abstract – Face acknowledgment is a standout amongst the most difficult subjects in PC vision today. It has applications running from security and observation to amusement sites. Face acknowledgment programming are valuable in banks, airplane terminals, and different organizations for screening clients. Germany and Australia have conveyed confront acknowledgment at outskirts and traditions for Automatic Passport Control. Human face is a dynamic protest having high level of fluctuation in its appearance which makes confront acknowledgment a troublesome issue in PC vision. In this field, precision and speed of ID is a principle issue. Numerous difficulties exist for confront acknowledgment. The power of the framework can be blocked by people who change their facial highlights through wearing hued make-up, putting on serious contact focal points, growing a mustache, putting on serious make-up, and so on. Moral concerns are additionally identified with the way toward recording, contemplating, and perceiving faces. Numerous people don’t endorse of observation frameworks which take various photos of individuals who have not approved this activity. The objective of this paper is to assess confront discovery and acknowledgment procedures and give a total answer for picture based face location and acknowledgment with higher exactness, better reaction rate and an underlying advance for video observation. Arrangement is proposed in light of performed tests on different face rich databases as far as subjects, stance, feelings and light.

Index Terms – Finger Print, DNA, Neural Networks, Computer Vision.

1. INTRODUCTION

Criminal record contains personal information about a particular person along with photograph. To identify any criminal we need identification regarding that person, which are given by the eyewitness. Identification can be done by finger print, eyes, DNA etc. One of the applications is face identification. The face is our primary focus of attention in social intercourse playing a major role in conveying identity and emotion. Although it is difficult to infer intelligence or character from facial appearance, the human ability to remember and recognize faces is remarkable.

A face recognition system uses a database of images and compares another image against those to find a match, if one exists. For each facial image, identification can be done using the RGB values for the eye color, the width and height of the face and also using various ratios which was done by Kovashka and Martonosi [1].

This system is aimed to identify the criminals in any investigation department. In this system, we are storing the images of criminals in our database along with his details and then these images are segmented into four slices- forehead, eyes, nose and lips. These images are again stored in another database record so as to make the identification process easier. Eyewitnesses will select the slices that appear on the screen and by using it we retrieve the image of the face from the database. Thus this system provides a very friendly environment for both the operator and the eyewitness to easily identify the criminal, if the criminals record exists in the database. This project is intended to identify a person using the images previously taken. The developed system is also a first milestone for video based face detection and recognition for surveillance.

2. CURRENT RESEARCH ON FACE RECOGNITION AND TECHNIQUES AVAILABLE

Key goal of computer vision researchers is to create automated face recognition systems that can equal, and eventually surpass, human performance. To this end, it is imperative that computational researchers know of the keyfindings from experimental studies of face recognition [1]. These findings provide insights into the nature of cues that the human visual system relies upon for achieving its impressive performance and serve as the building blocks for efforts to artificially emulate these abilities.

The face recognition problem has been studied for more than two decades. The approaches proposed in the literature so far can mainly be classified into two categories: model based and appearance based as described by Fu Jie Huang and Zhihua Zhou [5]. The model based method tries to extract geometrical parameters measuring the facial parts while the appearance based approach use the intensity or intensity-derived parameters such as eigen faces coefficients to recognize faces. Due to the changes of lighting condition, expression, occlusion, rotation, etc., the human face appearance could change considerably. Vetter [5]. The third method is the eigenspace from all of the different views, proposed by Murase and Nayar, and later used by Graham and Allinson in face recognition [5].

2.1 Two-Dimensional and Three-Dimensional Techniques

In the early years of the 21st century, we found ourselves continually moving further away from the necessity of physical human interaction playing a major part of everyday tasks. Striding ever closer to an automated society, we interact more frequently with mechanical agents, anonymous users and the electronic information sources of the World Wide Web, than with our human counterparts. It is therefore perhaps ironic that identity has become such an important issue in the 21st century.
It would seem that in an age where fraud is costing the public billions of pounds every year and even the most powerful nations are powerless against a few extremists with a flight ticket, it is not who we are that is important, but rather, that we are who we claim to be. For these reasons, biometric authentication has already begun a rapid growth in a wide range of market sectors and will undoubtedly continue to do so, until biometric scans are as commonplace as swiping a credit card or scrawling a signature [4].

### 2.2 Various categories of facial recognition algorithms:
- Neural networks.
- Feature analysis.
- Graph matching.
- Information theory.

Face recognition has a number of advantages over biometrics, it is non-intrusive. Whereas many biometrics require the subject's co-operation and awareness in order to perform an identification or verification, such as looking into an eye scanner or placing their hand on a fingerprint reader, face recognition could be performed even without the subject's knowledge as described by the NSTC Committee [4].

### 2.3 Face Recognition Techniques

The method for acquiring face images depends upon the underlying application. For instance, surveillance applications may best be served by capturing face images by means of a video camera while image database investigations may require static intensity images taken by a standard camera. Some other applications, such as access to top security domains, may even necessitate the forgoing of the nonintrusive quality of face recognition by requiring the user to stand in front of a 3D scanner or an infra-red sensor [4].

#### 2.3.1 Face Recognition from Intensity Images

Face recognition methods from intensity images fall into two main categories: feature-based and holistic. An overview of the well-known methods in these categories is given below.

##### 2.3.1.1 Featured-based

Feature-based approaches first process the input image to identify and extract (and measure) distinctive facial features such as the eyes, mouth, nose, etc., as well as other marks, and then compute the geometric relationships among those facial points, thus reducing the input facial image to a vector of geometric features. Standard statistical pattern recognition techniques are then employed to match faces using these measurements.

##### 2.3.1.2 Holistic

Holistic approaches attempt to identify faces using global representations, i.e., descriptions based on the entire image rather than on local features of the face. These schemes can be subdivided into two groups: statistical and AI approaches.

#### 2.3.1.3 Statistical

In the simplest version of the holistic approaches, the image is represented as a 2D array of intensity values and recognition is performed by direct correlation comparisons between the input face and all the other faces in the database. Though this approach has been shown to work under limited circumstances (i.e., equal illumination, scale, pose, etc.), it is computationally very expensive and suffers from the usual shortcomings of straightforward correlation-based approaches, such as sensitivity to face orientation, size, variable lighting conditions, background clutter, and noise.

#### 2.3.2 Predominant Approaches

There are two predominant approaches to the face recognition problem: geometric (feature based) and photometric (view based). As researcher interest in face recognition continued, many different algorithms were developed, three of which have been well studied in face recognition literature: Principal Components Analysis (PCA), Linear Discriminate Analysis (LDA), and Elastic Bunch Graph Matching (EBGM) [4].

##### 2.3.2.1 PCA:

Principal Components Analysis (PCA) is the technique pioneered by Kirby and Sirivich in 1988. With PCA, the probe and gallery images must be the same size and must be normalized to line up the eyes and mouth of the subjects within the images. The PCA approach is then used to reduce the dimension of the data by means of data compression and reveals the most effective low dimensional structure of facial patterns. This reduction in dimensions removes information that is not useful and precisely decomposes the face structure into orthogonal (uncorrelated) components known as eigen faces. Each face image may be represented as a weighted sum (feature vector) of the eigen faces, which are stored in a 1D array. A probe image is compared against a gallery image by measuring the distance between their respective feature vectors. The PCA approach typically requires the full frontal face to be presented each time, otherwise the image results in poor performance. The primary advantage of this technique is that it can reduce the data needed to identify the individual to 1/1000th of the data presented.

In the training phase, you should extract feature vectors for each image in the training set. Let A be a training image of person A which has a pixel resolution of $M \times N$ (M rows, N columns). In order to extract PCA features of A, you will first convert the image into a pixel vector $\tilde{A}$ by concatenating each of the M rows into a single vector. The length (or, dimensionality) of the vector $\tilde{A}$ will be $M \cdot EN$. In this project, you will use the PCA algorithm as a dimensionality reduction technique which transforms the vector $\tilde{A}$ to a vector $A$ which
has a dimensionality $d$. For each training image $i$, you should calculate and store these feature vectors $I$.

In the recognition phase (or, testing phase), you will be given a test image $J$ of a known person. Let $J$ be the identity (name) of this person. As in the training phase, you should compute the feature vector of this person using PCA and obtain $J$. In order to identify $J$, you should compute the similarities between $J$ and all of the feature vectors $I$’s in the training set. The similarity between feature vectors can be computed using Euclidean distance. The identity of the most similar $I$ will be the output of our face recognizer. If $I = J$, it means that we have correctly identified the person $J$, otherwise if $I' = J$, it means that we have misclassified the person $J$.

2.3.2.2 LDA: Linear Discriminant Analysis

LDA is a statistical approach for classifying samples of unknown classes based on training samples with known classes. (Figure 2) This technique aims to maximize between-class (i.e., across users) variance and minimize within-class (i.e., within user) variance. In Figure where each block represents a class, there are large variances between classes, but little variance within classes. When dealing with high dimensional face data, this technique faces the small sample size problem that arises where there are a small number of available training samples compared to the dimensionality of the sample space.

2.3.2.3 EBGM: Elastic Bunch Graph Matching

EBGM relies on the concept that real face images have many nonlinear characteristics that are not addressed by the linear analysis methods discussed earlier, such as variations in illumination (outdoor lighting vs. indoor fluorescents), pose (standing straight vs. leaning over) and expression (smile vs. frown). A Gabor wavelet transform creates a dynamic link architecture that projects the face onto an elastic grid. The Gabor jet is a node on the elastic grid, notated by circles on the image below, which describes the behavior around a given pixel. It is the result of a convolution of the image with a Gabor filter, which is used to detect shapes and to extract features using image processing.
of all pixels above and to the left of the concerned pixel. This is demonstrated in Figure

![Integral Image](image)

**Fig5. Transform Input image to Integral image**

This allows for the calculation of the sum of all pixels inside any given rectangle using only four values. These values are the pixels in the integral image that coincide with the corners of the rectangle in the input image. The Viola-Jones face detector analyzes a given sub-window using features consisting of two or more rectangles. Each feature results in a single value which is calculated by subtracting the sum of the white rectangle(s) from the sum of the black rectangle(s). Viola-Jones has empirically found that a detector with a base resolution of 24*24 pixels gives satisfactory results. When allowing for all possible sizes and positions of the features total of approximately 160,000 different features can then be constructed. Thus the amount of possible features vastly outnumbers the 576 pixels contained in the detector at base resolution. Following images are Screenshots from our systems module that is Face Recognition along with name of a corresponding face.

3. CONCLUSION AND FUTURE WORK

This system uses our implementation of a face recognition system using features of a face including colors, features and distances. Using its two degree of freedom, our system allows two modes of operation, one that results in very few false positives and another which results in few false negatives. We have demonstrated various concerns related to the face recognition process, such as the lighting and background conditions in which the facial images are taken. Our system could be improved in the future through the development of a face detection algorithm which is less prone to incorrectness, failure and performs well regardless of the skin color. A more extensive feature set would also prevent the chance of tricking the system through the alteration of facial features.
